# A New Secure Lightweight Authentication Protocol for NFC mobile Payment

## Reham Abdellatif Abouhogail

Electrical Quantities Metrology Dept., National Institute of standards (NIS), Egypt

**Abstract:** As mobile applications grow, securing these applications become an important factor for their success. Especially, when these applications are related to financial transactions. Nowadays, mobile payment that is based on NFC technology is considered one of these important topics. In this paper, we propose A New Secure and Lightweight Authentication Protocol for NFC mobile Payment (NSLA) protocol. NSLA protocol presents a new method to update the users' identities and the valid session keys, which preserves the privacy and ensures the integrity of the system. The presented performance analysis shows that NSLA protocol satisfies low computation overhead. Moreover, the security analysis proves that NSLA protocol has an immunity against replay attack, brute force attack, denial of service attack, and others types of attacks.

*Keywords*: Authentication protocols; Mobile payment; NFC technology; Non-repudiation; Privacy; Integrity.

## 1. Introduction

Near field communication (NFC) is a type of communication that facilitates the exchange and requests of data. NFC enables a little amount of data transfer through short range communication about ten centimeters. NFC has many applications. For example, applications in transportations, healthcare, and access control. In transportations, NFC has an application in e-ticketing like ticket booking, then link this booking with your electronic wallet. In healthcare, NFC can make the interaction between the patient and doctor, nurse, or pharmacist more easy. Like observing the amount of medicine, getting information about blood, and pressure. Moreover, NFC has an application in access control, which some authorities or universities can implement a system based on NFC technology to check the identities of the persons who have special access rights.

All these mentioned applications require at least verification for the three most important measuring security parameters, the availability, the integrity, and the confidentiality of the sent and received data. Otherwise, many problems can be occurred. Like mistake in airline booking in the transportation application, damage may affect the health of the patient in healthcare applications, and many other problems. However, the main application for NFC is the contactless payment. Nowadays, Security in contactless payment based NFC communication is considered a challenge. You have to protect your payment information and your identifying personal information [1], and you have to ensure the authenticity between the three shared entities. The three shared entities are the Authentication Server (AS), the Point of Sale (PS), and the NFC Mobile user (M). When AS, PS, and M can authenticate each other, this is called mutual authentication property. Mutual authentication property is very important factor in electronic payment, and is considered a metric of success for any transaction operation. This is because it ensures preventing fraudulent activity. Moreover, payment using

mobile devices produces some limitations, like: limitations in mobile devices, and limitations in memory storage. To satisfy acceptable mobile payment procedures, many models are proposed [2, 3, 4, 5, 6]. In this paper, we focus in the authentication protocols in NFC mobile payments, which a new authentication protocol is presented. The new proposed protocol satisfies lightweight computation overhead, and satisfies the essential security requirements like mutual authentication, non-repudiation, availability, and preventing the famous types of possible attacks like replay attack, data desynchronization attack, and denial of service attack. The main contributions of this paper are summarized in the following points:

- 1. The proposed protocol is a lightweight authentication protocol, which its computation overhead is considered lower than the other similar proposed protocols, which is considered a challenge in NFC mobile payment applications. As will be declared in the performance analysis section.
- 2. The proposed protocol presents a new method for updating the session keys and the users' identities which keep them secure, and difficult to be expected. Revealing one of the previous valid keys or one of the previous valid identities doesn't mean the ability to reveal the following session keys and the following identities. Because they are randomly updated,
- 3. The proposed protocol satisfies the privacy of the shared users without losing the non-repudiation property, which is almost considered a difficult task for similar proposed protocols.
- 4. NSLA protocol has an immunity against most famous types of attacks (denial of service attack, brute force attack, and replay attack). As will be declared in the security analysis section. In the following section the related work is presented. In Section 3, the NSLA protocol is presented. In Section 4, the performance analysis is presented, the security analysis is discussed in Section 5, and finally the conclusion is presented in Section 6.

## 2. Related Work

Many electronic payment protocols based NFC technology are proposed in number of recent researches [7, 8, 9, 10, 11, 12, 13, 14, 15]. Some of them are based on public key encryption like in [7, 8, 14]. Others are based on symmetric key encryption like in [9, 10, 11, 12, 13]. In [7], Mohamad Badra and et. al. proposed "A lightweight security protocol for NFC-based mobile payments". This proposed protocol is for mobile payment applications based on the NFC technology using public key encryption technique. The proposed protocol discussed two cases. The first case, when the point of sale, *PS*  has an internet connection. The second case, when the *PS* has no internet connection. The protocol satisfies the mutual authentication property depending on three shared parties, the mobile device, *M*, *PS* device, and the trusted third party, *TTP*. In this case, there are five steps, and four sent messages. Both of the mobile device *M* and the *PS* device generate a random number *RVSE*, and *RVPOS* respectively. The *TTP* generates a session key by applying a pseudo random function on the generated random number by the mobile device, the generated random number by the *PS*, the received identity of the mobile device, and the XORing of the secret key between the *TTP* and the user *M*, SKTTP\_SE with the secret key between *PS* and *M*, SKPOS\_SE user. We are interested in the first case, because it's similar to our proposed protocol. In this case, this protocol proceeds as the following equations:

$$MSG\#1: M \to PS:ID_M, RV_{SE}.$$
(1)

$$MSG#2:PS \to TTP:ID_{PS}, RV_{SE}, Cert_{PS}.$$
(2)

 $MSG#3:TTP \rightarrow PS:EP(Session_key|| SKPOS_SE) \quad pubPS.$ (3);

where pub<sub>PS</sub> is the public key of the point of sale.

$$MSG#4:PS \to M:E_{S}(Session\_key, SK_{PS\_SE})$$
(4)

The PS sends its certificate (Cert<sub>PS</sub>) to the TTP. The TTP sends an asymmetric encrypted message to PS contains the session key and  $SK_{POS SE}$  using the PS's public key. The PS sends the session key to M symmetrically encrypted by SK<sub>POS\_SE</sub>. In step number 5, as proposed in this protocol, the mobile device has to compute the session key. Here, there is a certain problem, M hasn't the required data to compute the session key. It hasn't the SKPOS\_SE. Because, it's generated by the TTP, and the TTP is sent it to the PS asymmetrically encrypted by the PS's public key in MSG#3. Moreover, M doesn't know the RV<sub>POS</sub>.  $RV_{POS}$  is generated by the PS and is sent to the TTP only in MSG #2. To solve this problem, we propose that the PS replace the symmetric encryption used in MSG #4 by the asymmetric encryption using the mobile device public key. However, this will lead to a computation overhead problem due to the limited capability for the mobile devices. Moreover, sending the real identity of the NFC users violates the privacy. In [13], Ceipidor et.al.'s scheme proposed a protocol called KerNeeS, this protocol is based on Needham\_Schroeder symmetric key protocol. It satisfied the mutual authentication. However, sending the identities of the entities makes it vulnerable to tracking attack. In [9], a Secure and Efficient Mutual Authentication Scheme for NFC Mobile Devices is proposed. The authentication phase of this protocol consists of five messages. The session keys are updated. Therefore, forward and backward secrecy are satisfied. The protocol is a lightweight protocol. But, this protocol has some drawbacks: 1- the privacy and the non-repudiation properties are not satisfied in this protocol. 2- the message sent from the server to the point of sale and the last message sent from the point of sale to the mobile have no identity. It's only an output of MAC function, which making it difficult for the receiver (either PS or M) to determine the identity of the sender especially for the PS, which deals with more than mobile user. As it's known, PS has to know this message is belonged to which mobile user to extract the required data from its database, and calculates

the MAC function to make the required comparison with the received MAC. In [11], a SAP-NFC protocol is proposed. The protocol is performed between three entities, the NFC mobile, the point of sale, and the authentication server. The mutual authentication is satisfied between these three shared entities. This protocol proposes a solution to data desynchronization attack. The privacy property is satisfied in this protocol. However, SAP-NFC protocol has a problem with the non-repudiation property; it is not satisfied. Moreover, it's vulnerable to brute force attack, and denial of service attack.

#### 3. The Proposed Protocol (NSLA Protocol)

In this section, we propose a new and lightweight authentication protocol applicable for mobile payments applications using NFC technology. The proposed NSLA protocol consists of three entities. They are two NFC devices, the NFC mobile device, M, and the point of sale device, PS, and the authentication server, AS. NSLA protocol contains two phases, the registration phase and the authentication phase as shown in Fig.1. Table1 presents the important notations in our protocol.

Table 1. Notations

NotationMeaningASAuthentication Server $M_i$ NFC mobile device $i$ $PS_i$ Point of sale $i$ $ID_M^i$ , and $ID_{PS}^i$ Identity of the NFC mobile, and identity of the point of sale, respectively. $I_M^i$ , and $I_{PS}^i$ pseudonym of the NFC mobile $i$ and pseudonym of the NFC mobile $i$ and pseudonym of the point of sale $i$ respectively; where $i=0, 1,, n$ . $P_M^i / P_{PS}^i$ a pseudo random number assigned for the NFC mobile session key , and point of sale, respectively. $K_M^i$ , and $K_{PS}^i$ NFC mobile session key , and point of sale session key generated by the authentication server, respectively; where $i=0, 1,, n$ . $RI$ Nonce random number generated by $M/PS$ during the registration phase. $R2$ Nonce random number generated by $AS$ during the registration phase. $N1$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N2$ Nonce random number generated by $AS$ during the authentication phase. $N4$ Symmetric tey pecryption function for the message $m$ using the key $k$ .<	Table 1. 	$C_M$ and $C_{PS}$	Two confirmation messages are computed by the <i>AS</i> for the <i>M</i> and <i>PS</i> respectively.				

Figure 1. The registration phase in NSLA protocol.

Figure 2. The authentication phase in the NSLA protocol.

#### A. Registration phase

In this phase, we assume that the NFC mobile device  $M_i$  or  $PS_i$  performs the registration procedures with the Authentication Server (*AS*) through a secure channel. The secure channel is used for the registration phase only. The registration phase isn't frequently repeated as the authentication phase. So this assumption will not cause heavy processing in the system. Moreover, it increases the confidence level in the obtained data. The steps of registration are as follows:

$$MSG#1: M_i/PS_i \to AS: ID_M^i/ID_{PS}^i, R1$$
(5)

$$MSG#2:AS \to M_i/PS_i: I_M^i/I_{PS}^i, R2, K_M^i/K_{PS}^i, P_M^i/P_{PS}^i$$
(6)

where;  $I_M^i$  is the pseudonym of the NFC mobile,  $I_{PS}^i$  is the pseudonym of the point of sale, and  $I_M^i/I_{PS}^i = H(ID_M^i/ID_{PS}^i||RN)$ ; where *RN* is a generated random number by *AS*, and  $P_M^i/P_{PS}^i$  is a pseudo random number, its period (length) is determined according to the required level of security. Its period increases as the required level of security increases. However, you have a more communication overhead for long  $P_n$ . So here, there's a tradeoff. Hence, the *AS* has to have a good pseudo random number generator to generate random numbers for each NFC user. Each three bits in this  $P_n$  forms a number. The NFC device uses these numbers in order to update its own data.

For Example: if certain NFC device is given a pseudo random number,  $P_n$ ; where  $P_n = 001\ 110\ 010\ 111\ 000\ 011\ 100\ 101$ . So the required number of hash operations are = 1, 6, 2, 7, 0, 3, 4, 5 in order after each successful payment operation. Therefore, according to this order of numbers, this NFC device has to hash its pseudonym and its session key after the first successful payment operation one time to get its new pseudonym and its new session key, and after the second successful payment operation, the NFC device has to apply the hash function six times to the last pseudonym and last session key to get its new pseudonym and its new session key, and after the third successful payment operation apply the hash function two times, and etc.

After the NFC mobile device receives MSG#2, it stores  $I_M^i/I_{PS}^i$ ,  $K_M^i/K_{PS}^i$ , and  $P_M^i/P_{PS}^i$  in its database, and prepares MSG#3 to send it to AS.

MSG#3:
$$M_i/PS_i \rightarrow AS: MAC(R2, K_M^i/K_{PS}^i)$$
 (7)  
After receiving MSG#3, AS calculates  $MAC(R2, K_M^i/K_{PS}^i)$ ,  
and compares the result with the received one to verify the  
integrity of  $K_M^i/K_{PS}^i$ . To be sure that the following  
authentication verification steps will be happened correctly,  
you must be sure on the correctness of this key.

Note that  $I_M^i/I_{PS}^i$  and  $K_M^i/K_{PS}^i$  are changed after each successful payment operation or after number of successful payment operations according to the management of the system. By computing its hash value *l* number of times; where *l* equals certain digit number in the pseudo random number for this NFC device according to the order. After registration, the *AS* stores  $I_M^i/I_{PS}^i$ ,  $K_M^i/K_{PS}^i$ , and  $P_M^i/P_{PS}^i$  in its database. Moreover, the *AS* still keep  $I_M^i$ , and  $K_M^i$  after updating them to satisfy the non\_repudiation property. The three shared entities in the protocol *AS*, *PS<sub>i</sub>*, and *M<sub>i</sub>* are ready now to proceed into the authentication phase as presented in the following Subsection.

#### **B.** Authentication phase

After the registration phase, both of  $M_i$  and  $PS_i$  own the required data to begin the authentication phase as shown in Fig.2, the procedures will be as follows.

The *PS<sub>i</sub>* sends MSG#1 to  $M_i$ , which contains a generated random number *NI* and the *PS*'s pseudonym  $I_{PS}^i$ .

1. MSG#1: 
$$PS_i \rightarrow M_i$$
:  $I_{PS}^i$ , N1 (8)  
After receiving MSG#1,  $M_i$  generates N2, and computes the

verification message,  $V_M$ ; where  $V_M = MAC(I_M^i ||N1||N2, K_M^i)$ . Then,  $M_i$  sends MSG#2.

2. MSG#2: 
$$M_i \rightarrow PS_i$$
:  $I_M^i$ , N1, N2,  $V_M$  (9)

After receiving MSG#2,  $PS_i$  computes the verification message,  $V_{PS}$ ; where  $V_{PS} = MAC(I_{PS}^i||N1||N2, K_{PS}^i)$ . Then,  $PS_i$  sends MSG#3.

3. MSG#3:  $PS_i \rightarrow AS: I_{PS}^i I_M^i, N2, N1, V_{PS}, V_M$  (10) After receiving MSG#3, AS computes  $V_M$  and  $V_{PS}$  using the stored  $I_M^i/I_{PS}^i, K_M^i/K_{PS}^i$ , and  $P_M^i/P_{PS}^i$  in its database. Then, AS compares the received values with the computed values, and checks the results. If the computed  $V_M$  or the computed  $V_{PS}$  is not equal the received  $V_M$  and the received  $V_{PS}$ , the AS ends the session, else  $M_i$  and  $PS_i$  are verified. Then, AS prepares a confirmation messages,  $C_{PS}$  and  $C_M$ ; Where  $C_{PS} =$  $MAC(I_{PS}||I_M||N1||N2, K_{PS}^0), C_M =$ 

 $MAC(I_{PS}||I_M|N1||N2, K_{MS}^0)$ . Then, AS sends MSG#4.

4. MSG#4:
$$AS \rightarrow PS_i: N1, C_M, C_{PS}$$
 (11)  
After receiving MSG#4,  $PS_i$  computes  $C_{PS}$ , and checks if the

After receiving MSG#4,  $PS_i$  computes  $C_{PS_i}$  and checks if the computed value equals the received one. If the check is fail,  $PS_i$  closes the session else  $PS_i$  authenticates  $M_i$ , and AS. Then, PSi sends MSG#5 to  $M_i$ .

5. MSG#5: 
$$PS_i \rightarrow M_i : N2, C_M$$
 (12)

After receiving MSG#5,  $M_i$  computes  $C_M$  and compares the computed  $C_M$  with the received  $C_M$ . If they are not equal,  $M_i$  closes the session else  $M_i$  verifies  $PS_i$  and AS. Note: to proceed into a new authentication phase,  $M_i$  and  $PS_i$  has to update their pseudonyms  $I_M^i/I_{PS}^i$  and their session keys  $K_M^i/K_{PS}^i$  by hashing them number of times according to their pseudo random number  $P_M^i/P_{PS}^i$  as declared before. Also, the AS has to update the required data for each NFC device participates in the system using the stored NFC device's pseudo random number. The following section presents a performance analysis for the proposed protocol with a comparison to its similar lightweight authentication protocols.

 Table 2 The computation time for different cryptographic operations [16].

Number of mutual messages during the authentication phase.	7	5	5	5

## 4. Performance Analysis and Comparison

In this section, analysis for the performance of NSLA protocol from several characteristics is presented, including computation overhead, computation time, and number of required messages, M, by comparing it with other schemes which are the most relevant to ours [9, 10, and 13]. The three selected authentication protocols [9, 10, and 13] are based on

NFC technology. In addition to, they didn't resort to use an asymmetric key technique in their proposed design. So they considered lightweight authentication protocols. are Moreover, they contain three shared entities, two NFC devices, and an authentication server which made them more suitable for comparison with our proposed protocol. To calculate the computation cost (ms), we used the estimated computation time for different cryptographic operations, which are presented in Table 2 [16]. Performance comparison is presented in Table 3. We assume some assumptions as shown in Table 2: 1- The data size for all functions are assumed to be the same, 2- The processing time for the symmetric encryption function  $E_s$  equals the processing time for the symmetric decryption function  $D_s$ , 3- The processing time for the asymmetric encryption function  $E_P$  equals the processing time for the asymmetric decryption function  $D_P$ ,4-The processing time for the hash function equals the processing time for the MAC function.

According to the results presented in Table 2, we can see that NSLA protocol has good results between the other presented schemes. Our protocol doesn't require the mobile device to do any heavy processing during payments, which is considered more suitable for mobile devices which have limited power. From Table 2, we can see that Tung and Juang's protocol [9] has the same number of mutual messages as the NSLA proposed protocol, and it has less computation overhead. But, Tung and Juang's protocol [9] lacks two important security features, which are the privacy, and the non-repudiation as was declared in Section 2.

#### 5. Security Analysis and Comparison

In this section, the security analysis is presented, the analysis is based on the main security requirements.

#### **5.1 Mutual Authentication**

The presented protocol assumes that the authentication channel between the shared entities is susceptible to attacks. Therefore, the NSLA protocol follows some steps to defend itself. To satisfy authentication between the three shared entities, the protocol uses a MAC functions, verification messages, and confirmation messages. In the beginning, AS searches in its pseudonym database list for the received pseudonyms,  $I_M^i$  and  $I_{PS}^i$ . If they are existed the AS can get the corresponding data for these pseudonyms like the session keys,  $K_M^l$ ,  $K_{PS}^l$  and the pseudo random numbers  $P_M^l/P_{PS}^l$ . Otherwise, the  $M_i$  or the  $PS_i$  is considered not legitimate. After that, the AS verifies if the received VPS or  $V_M$  is equal to the received ones. If the calculated  $V_M$  or  $V_{PS}$  doesn't equal to the received values then the AS will consider the  $M_i$  or the  $PS_i$  is not legitimate, and the authentication session is terminated. On the other side,  $PS_i$  verifies if the received  $C_{PS}$  equals the calculated value. If the verification fails, the AS will be considered not legitimate, and the  $PS_i$  terminates the session. On the same approach,  $M_i$  verifies that the received  $C_M$  equals the calculated one. If the verification fails,  $PS_i$  will be considered not legitimate, and  $M_i$  terminates the session.

#### 5.2 Preserving user anonymity

No adversary can verify which pseudonym corresponds to the given user identity due to the difficulty of solving the hash function; where the identity of the user is hashed with certain random number. Furthermore, these pseudonyms are updated after number of success payment operations as mentioned before.

## 5.3 Integrity

Integrity is satisfied by using MAC functions with secure and periodically updated session key.

## 5.4 Forward and Backward secrecy for key

The forward and backward secrecy for the user's key is satisfied. The adversary can't know the user's key. Because, the user's key is transmitted through a secure channel. Moreover, it's updated after each successful payment as mentioned before. However, Kernees protocol, which is presented in [13], the old sessions keys are valid.

#### 5.5 Immunity against attacks

In this subsection, the most important and related types of attacks to the subject of the presented protocol are analyzed to assess their potential.

#### 5.5.1 Denial of service attack

Other protocols like SAP-NFC protocol [11] suffer from a denial of service attack. Because upon the AS server receives the challenge messages from either the NFC mobile or the PS, it computes a hash function for all the stored mobiles' identities or all the stored PSs' identities until it finds the required match. Hence, the denial of service attack is possible by making the AS busy all the time in calculating a lot of hash functions responding to these erroneous received messages. In our presented protocol, this problem is solved; which the AS receives the hashed message (the pseudonym) and stores the pseudonyms in its database. Therefore, the denial of service attack is improbable.

#### 5.5.2 Man in the middle attack

As long as the mutual authentication is satisfied as mentioned before, the adversary hasn't the ability to impersonate the legitimate users.

#### 5.5.3 Replay attack

The replay attack to be probable, the adversary must know the valid session key with its corresponding pseudonym, and this's considered very difficult. Because, the session keys and the pseudonyms are updated regularly.

#### 5.5.4 Desynchronization attack

NSLA protocol doesn't need time synchronization. Therefore, data desynchronization attack is improbable.

#### 5.5.5 Brute force attack

Our presented scheme has high level of immunity against brute force attack. This is due to updating the used session key after number of success payments as mentioned. Moreover, our proposed design updating the key according to random rule. So even if the key is revealed, the adversary still can't guess the used key in the following session, and so on. In other presented protocols [10,11], which use the KDF function or hash function only to generate the key, if the current session key is revealed, it will be easy to know the following session key by making simple hash function.

## 5.6 Non-repudiation

In the presented NSLA protocol, the *AS* stores the pseudonyms and their corresponding valid session keys after updating them for a certain time to satisfy the non-repudiation property. Other protocols like SAP-NFC protocol [10] the non-repudiation property is not satisfied. Where, the *AS* updates its database immediately as soon as the NFC user's data are updated.

#### 5.7 Security features comparison

In this subsection, we summarize all the results that we have reached to after the discussion, that is presented in the previous subsections. Table 4 presents a comparison between the presented NSLA protocol, and the authentication protocols which are presented in [9, 10, and 13]. The proposed protocol in [9] mentioned that the session keys are updated without determine the method that is used to update them. So we use the notation (=) in Table 4 to refer to the security feature that isn't exactly determined.

Table 4. Security features comparison b	between different
NFC authentication protoc	ols.

#### 5.8. Formal analysis using BAN logic

In this subsection a formal verification of the proposed protocol is presented to ensure its validity. BAN Logic [17] for verification of authentication protocols is used. BAN logic is selected because of its excellence to prove the mutual authentication between the shared entities. Moreover, its ability to detect number of attacks like the replay attack.

#### **Rules of BAN Logic**

4.

1. Rule 1 : the interpretation rule,  $P \models (Q \mid \sim (X, Y))$ 

$$P \models (Q \mid \sim X), P \models (Q \mid \sim Y)$$

- 2. Rule 2 : the message meaning rule,  $\frac{P \models P \xleftarrow{\kappa} Q, P \triangleleft [X]_{\kappa}}{P \models Q \mid \sim X}, P \neq Q$
- 3. Rule 3 : the nonce verification rule,  $\underline{P \models \#(X), P \models Q \sim X}$

$$P \models Q \models X$$

Rule 4: the jurisdiction rule,  $\frac{P \models Q \Rightarrow X, P \models Q \models X}{P \models X}$ 

5. Rule 5: the freshness rule,  

$$P \models \#(X)$$

$$P \models \#(X,Y)$$

6. Rule 6: the synthetic rule,  $P \models (Q \mid \sim X) \rightarrow P \models (Q \mid \sim (X,Y))$ 

7. Rule 7: 
$$\frac{P \in (X,Y)}{P \in (X), P \in (Y)}$$

The authentication protocol is completed between *AS* and *PS*, if for certain data *X*:

 $AS \models PS \models X$ ,  $AS \models X$ : they mean that AS believes that X is sent by PS; where symbol  $\models$  means believes. Also, the authentication protocol is completed between AS and M, if for certain data Y:  $AS \models M \models Y$ ,  $AS \models Y$ : they mean that ASbelieves that Y is sent by M. The messages of the 111

authentication phase of the NSLA protocol can be transformed into the following formulas:

The first message is omitted, because all its components are plaintext.

$$M \to PS: I_M, \#N1, \#N2, (I_M, \#N1, \#N2)_{K_m}$$
 (13)

$$PS \to AS: I_M, I_{PS}, N1, \\ \#N2, (I_M, \#N1, \#N2)_{K_{m\nu}}, (I_{ps}, \#N1, \#N2)_{K_{ps}}$$
(14)

$$AS \rightarrow PS: N1, (I_M, I_{PS}, \#N1, \#N2)_{K_m}$$

$$(I_M, I_{PS}, \#N1, \#N2)_{K_{pS}}$$
 (15)

$$PS \to M: \#N2, \ (I_M, I_{PS}, \#N1, \#N2)_{K_m}$$
 (16)

These are the initial assumptions:

 $AS \equiv AS \xrightarrow{K_m} M$ (17) $M \models AS \xrightarrow{K_m} M$ (18)

$$PS \models AS \xrightarrow{K_{ps}} PS$$
(19)

$$AS \models AS \xrightarrow{K_{ps}} PS$$
(20)

$$AS \models \# N1 \tag{21}$$
  
$$AS \models \# N2 \tag{22}$$

$$AS \models PS \Rightarrow I_{PS} \tag{23}$$

$$AS \models M \Rightarrow I_M \tag{24}$$

 $M \models AS \Rightarrow I_M$ (25)

$$PS \models AS \Rightarrow I_{PS}$$
(26)  

$$PS \models \# N1$$
(27)  

$$M \models \# N2$$
(28)

 $AS \equiv M \mid \sim (I_M, N1, N2)$ (29)

Using Equation (14) and Equation (20) and after applying the message meaning rule, we obtain:

$$AS \models PS|\sim (I_{PS}, N1, N2) \tag{30}$$

Using Equation (30) and applying the interpretation rule, we obtain:

$$AS \models PS |\sim (N1, I_{PS}) \tag{31}$$

Using Equation (31) and applying the freshness rule, we obtain:

$$AS \vDash \#(N1, I_{PS}) \tag{32}$$

Using Equation (31 and 32) and applying the nonce verification rule, we obtain:

 $AS \equiv PS \equiv (N1, I_{PS})$ (33)From Equation (33) and from rule 7 (34)

 $AS \equiv PS \equiv I_{PS}$ 

From Equation (34, and 23) and from the jurisdiction rule, we obtain:

$$AS \equiv I_{PS} \tag{35}$$

From Equations (34 and 35), we can say that PS is the actual sender of the messages. So AS authenticates PS. The same steps will be done to proof that AS authenticates M as follows: Using Equation (30) and applying the interpretation rule, we obtain.

$$AS \models M \mid \sim (N2, I_M) \tag{36}$$

Using Equation (36) and applying the freshness rule, we obtain:

$$AS \vDash \#(N2, I_M) \tag{37}$$

Using Equations (37 and 36) and applying the nonce verification rule, we obtain:

$$AS \models M \models (N2, I_M) \tag{38}$$

From Equation (38) and from rule 7, we obtain  

$$AS \equiv M \equiv I_M$$
 (39)

From Equations (39, and 24) and from the jurisdiction rule, we obtain:

$$AS \models I_M \tag{40}$$

From Equations (39 and 40), we can say that M is the actual sender of the messages. So AS authenticates M.

Now, we will use BAN logic to verify that M and PSauthenticate AS to verify that the mutual authentication is verified in NSLA protocol.

By dividing Equation (15) into three parts, and by using Equation (16) we can get the following three Equations:

$$AS \to PS: \#N1, (I_m, I_{ps}, \#N1, \#N2)_{K_m}$$
 (41)

$$AS \to M: \left(I_m, I_{ps}, \#N1, \#N2\right)_{K_m} \tag{42}$$

$$AS \to PS: \left(I_m, I_{ps}, \#N1, \#N2\right)_{K_{ps}}$$
(43)

From Equation (42) and Equation (19) and after applying the message meaning rule, we obtain:

$$M \models AS \mid \sim (I_M, I_{PS}, N1, N2) \tag{44}$$

Using Equation (44) and applying the interpretation rule, we obtain:

$$M \equiv AS \mid \sim (I_M, N2) \tag{45}$$

Using Equation (45 and 28) and after applying the freshness rule, we obtain:

$$M \models \#(I_M, N2) \tag{46}$$

Using Equations (45 and 46) and applying the nonce verification rule, we obtain:

$$M \equiv AS \equiv (I_M, N2) \tag{47}$$

From Equation (47) and from rule 7, we obtain  $M \equiv AS \equiv I_M$ (48)

From Equations (48, and 25) and from the jurisdiction rule, we obtain:

$$M \equiv I_M \tag{49}$$

From Equations (48 and 49), we can say that AS is the actual sender of the messages. So M authenticates AS.

From Equation (43) and Equation (19) and after applying the message meaning rule, we obtain:

$$PS \equiv AS \mid \sim (I_M, I_{PS}, \#N1, \#N2)$$
(50)

Using Equation (50) and applying the interpretation rule, we obtain:

$$PS \models AS \mid \sim (I_{PS}, N1) \tag{51}$$

Using Equations (51, and 27) and after applying the freshness rule, we obtain:

$$PS \models \#(I_{PS}, N1) \tag{52}$$

Using Equations (51 and 52) and applying the nonce verification rule, we obtain:

$$PS \models AS \models (I_{PS}, N1) \tag{53}$$

From Equation (53) and from rule 7, we obtain  $PS \equiv AS \equiv I_{PS}$ 

$$PS \equiv AS \equiv I_{PS}$$
 (54)  
From Equations (54, and 26) and from the jurisdiction rule, we obtain:

$$PS \equiv I_{PS}$$
 (55)

From Equations (54 and 55), we can say that AS is the actual sender of the messages. So PS authenticates AS. From the previous analysis and from the properties of BAN logic, we can say that the mutual authentication between the shared entities in the NSLA protocol is verified. Moreover, we can say that NSLA protocol has no redundancy, and it's free from any type of known attacks like, replay attack, and man in the middle attack.

# 6. Conclusions

Today, many people use electronic payment. Later, mobile payment especially using NFC technology will spread widely as it's expected. Therefore, it's necessary to provide a safe environment for this use. With the large number of vulnerabilities in this media, it's considered not an easy task. In this paper, NSLA authentication protocol is proposed. The design of NSLA protocol assume updating for the used session keys, and the users' pseudonyms which making NSLA satisfy some essential properties, the privacy, and forward backward secrecy. A new method to update the session keys, and the users' pseudonyms is presented. This method is characterized by its randomness in generating the session keys, and the users' pseudonyms, which gives the NSLA protocol immunity against brute force attack. The security analysis proves that NSLA satisfies the mutual authentication between the shared entities, and it has an immunity against most types of attacks. The performance analysis proves that NSLA is lightweight compared to other recent proposed authentication protocols based NFC technology. So it's more suitable for NFC mobile payment application.
